# Docker – Containerization

#### Docker

It is a set of platform as a service products that use OS-level virtualization to deliver software in packages called containers. Containers are isolated from one another and bundle their own software, libraries and configuration files; they can communicate with each other through well-defined channels

#### Containerization

It is a form of virtualization where applications run in isolated user spaces, called containers, while using the same shared operating system (OS). A container is essentially a fully packaged and portable computing environment.

Everything an application needs to run—its binaries, libraries, configuration files, and dependencies—is encapsulated and isolated in its container. The container itself is abstracted away from the host OS, with only limited access to underlying resources—much like a lightweight virtual machine (VM). As a result, the containerized application can be run on various types of infrastructure—on bare metal, within VMs, and in the cloud—without needing to refactor it for each environment.

With containerization, there's less overhead during start-up and no need to set up a separate guest OS for each application since they all share the same OS kernel. Because of this high efficiency, containerization is commonly used for packaging up the many individual microservices that make up modern apps.

#### **Docker Image**

A Docker image is a file used to execute code in a Docker container. Docker images act as a set of instructions to build a Docker container, like a template. Docker images also act as the starting point when using Docker. An image is comparable to a snapshot in virtual machine (VM) environments.

Docker images have multiple layers, each one originates from the previous layer but is different from it. The layers speed up Docker builds while increasing reusability and decreasing disk use. Image layers are also read-only files. Once a container is created, a writable layer is added on top of the unchangeable images, allowing a user to make changes.

#### **Use Cases**

A Docker image has everything needed to run a containerized application, including code, config files, environment variables, libraries and runtimes. When the image is deployed to a Docker environment, it can be executed as a Docker container. The docker run command creates a container from a specific image. Docker images are a reusable asset -- deployable on any host. Developers can take the static image layers from one project and use them in another. This saves the user time, because they do not have to recreate an image from scratch.

#### Dockerfile

Docker can build images automatically by reading the instructions from a Dockerfile. A Dockerfile is a text document that contains all the commands a user could call on the command line to assemble an image. Using docker build users can create an automated build that executes several command-line instructions in succession.

#### Microservices Dockerfile:

1. Cloud-Gateway:

Link: <a href="https://github.com/2020HS-DevOps-Group3/Shop-Microservices/blob/main/cloud-gateway/Dockerfile">https://github.com/2020HS-DevOps-Group3/Shop-Microservices/blob/main/cloud-gateway/Dockerfile</a>

FROM openidk:11

**EXPOSE 8080** 

ADD target/cloud-gateway-0.0.1-SNAPSHOT.jar cloud-gateway-0.0.1-SNAPSHOT.jar

ENTRYPOINT ["java","-jar","/cloud-gateway-0.0.1-SNAPSHOT.jar"]

## 2. Order-Service:

Link: <a href="https://github.com/2020HS-DevOps-Group3/Shop-Microservices/blob/main/order-service/Dockerfile">https://github.com/2020HS-DevOps-Group3/Shop-Microservices/blob/main/order-service/Dockerfile</a>

FROM openidk:11

**EXPOSE 8081** 

ADD target/order-service-0.0.1-SNAPSHOT.jar order-service-0.0.1-SNAPSHOT.jar

ENTRYPOINT ["java","-jar","/order-service-0.0.1-SNAPSHOT.jar"]

### 3. Payment-Service:

Link: <a href="https://github.com/2020HS-DevOps-Group3/Shop-Microservices/blob/main/payment-service/Dockerfile">https://github.com/2020HS-DevOps-Group3/Shop-Microservices/blob/main/payment-service/Dockerfile</a>

FROM openidk:11

**EXPOSE 8082** 

ADD target/payment-service-0.0.1-SNAPSHOT.jar payment-service-0.0.1-SNAPSHOT.jar

ENTRYPOINT ["java","-jar","/payment-service-0.0.1-SNAPSHOT.jar"]

#### 4. Product-Service:

Link: <a href="https://github.com/2020HS-DevOps-Group3/Shop-Microservices/blob/main/product-service/Dockerfile">https://github.com/2020HS-DevOps-Group3/Shop-Microservices/blob/main/product-service/Dockerfile</a>

FROM openidk:11

**EXPOSE 8083** 

ADD target/product-service-0.0.1-SNAPSHOT.jar product-service-0.0.1-SNAPSHOT.jar

ENTRYPOINT ["java","-jar","/product-service-0.0.1-SNAPSHOT.jar"]

#### 5. Service-Registry:

Link: <a href="https://github.com/2020HS-DevOps-Group3/Shop-Microservices/blob/main/service-registry/Dockerfile">https://github.com/2020HS-DevOps-Group3/Shop-Microservices/blob/main/service-registry/Dockerfile</a>

FROM openjdk:11

**EXPOSE 8761** 

ADD target/service-registry-0.0.1-SNAPSHOT.jar service-registry-0.0.1-SNAPSHOT.jar

ENTRYPOINT ["java","-jar","/service-registry-0.0.1-SNAPSHOT.jar"]

#### **Docker Compose**

Compose is a tool for defining and running multi-container Docker applications. With Compose, you use a YAML file to configure your application's services. Then, with a single command, you create and start all the services from your configuration.

Using Compose is basically a three-step process:

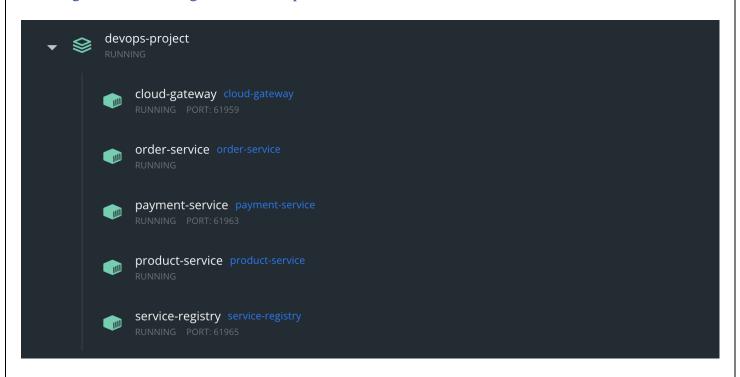

- 1. Define your app's environment with a Dockerfile so it can be reproduced anywhere.
- 2. Define the services that make up your app in docker-compose.yml so they can be run together in an isolated environment.
- 3. Run docker compose up and the Docker compose command starts and runs your entire app. You can alternatively run docker-compose up using the docker-compose binary.

# docker-compose.yml

Link: <a href="https://github.com/2020HS-DevOps-Group3/Shop-Microservices/blob/main/docker-compose.yml">https://github.com/2020HS-DevOps-Group3/Shop-Microservices/blob/main/docker-compose.yml</a>

# Running containers using Docker-Compose

# Continuous Integration/Continuous Deployment

# Building CI/CD

For Continuous Integration and Continuous Deploy we used Jenkins.

#### Jenkins:

It is an open source automation server. Jenkins helps automate the parts of software development related to building, testing, and deploying, facilitating continuous integration and continuous delivery. It is a server-based system that runs in servlet containers such as Apache Tomcat.

#### Jenkins Pipeline:

It is a suite of plugins which supports implementing and integrating *continuous delivery pipelines* into Jenkins.

# Why Pipeline?

Jenkins is, fundamentally, an automation engine which supports a number of automation patterns. Pipeline adds a powerful set of automation tools onto Jenkins, supporting use cases that span from simple continuous integration to comprehensive CD pipelines. By modelling a series of related tasks, users can take advantage of the many features of Pipeline:

- **Code**: Pipelines are implemented in code and typically checked into source control, giving teams the ability to edit, review, and iterate upon their delivery pipeline.
- **Durable**: Pipelines can survive both planned and unplanned restarts of the Jenkins controller.
- **Pausable**: Pipelines can optionally stop and wait for human input or approval before continuing the Pipeline run.
- **Versatile**: Pipelines support complex real-world CD requirements, including the ability to fork/join, loop, and perform work in parallel.
- **Extensible**: The Pipeline plugin supports custom extensions to its DSL and multiple options for integration with other plugins.

## Pipeline-as-code:

Pipeline provides an extensible set of tools for modelling simple-to-complex delivery pipelines "as code" via the Pipeline domain-specific language (DSL) syntax.

The definition of a Jenkins Pipeline is written into a text file (called a Jenkinsfile) which in turn can be committed to a project's source control repository.

This is the foundation of "Pipeline-as-code"; treating the CD pipeline a part of the application to be versioned and reviewed like any other code.

Creating a Jenkinsfile and committing it to source control provides a number of immediate benefits:

- Automatically creates a Pipeline build process for all branches and pull requests.
- Code review/iteration on the Pipeline (along with the remaining source code).
- Audit trail for the Pipeline.
- Single source of truth for the Pipeline, which can be viewed and edited by multiple members of the project.

While the syntax for defining a Pipeline, either in the web UI or with a Jenkinsfile is the same, it is generally considered best practice to define the Pipeline in a Jenkinsfile and check that in to source control. Declarative versus Scripted Pipeline syntax

A Jenkinsfile can be written using two types of syntax - Declarative and Scripted.

#### Declarative Pipelines:

It is a more recent feature of Jenkins Pipeline which:

- provides richer syntactical features over Scripted Pipeline syntax, and
- is designed to make writing and reading Pipeline code easier.

Many of the individual syntactical components (or "steps") written into a Jenkinsfile, however, are common to both Declarative and Scripted Pipeline.

 post {
  always {
   sh 'docker logout'
```

# Jenkins Build Output:

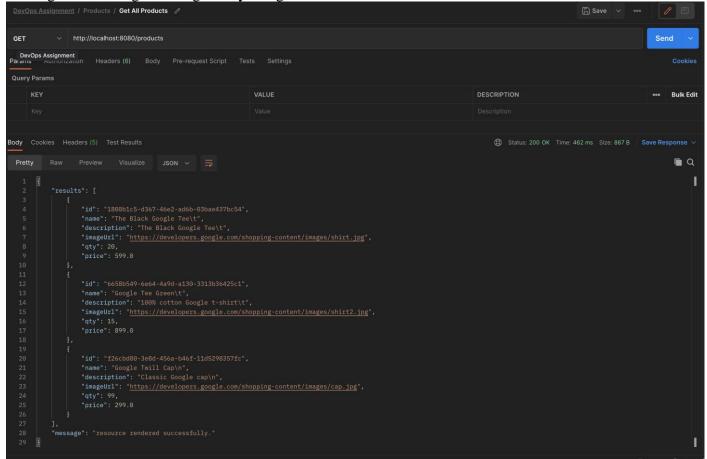

The Deployment stage could have been parallel, i.e. the deployment of service could have been concurrent but due to having a free tier account of Docker Hub multiple connections was not possible. Hence decided to do in series itself.

# DevOps Maturity in our project.

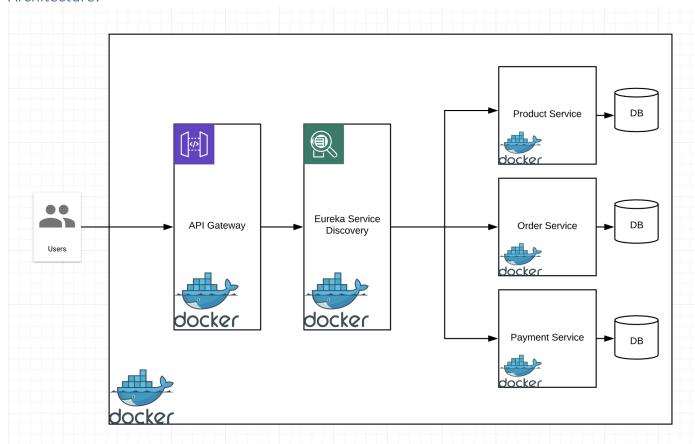

# Describe Project:

The project is Shopping webapp with the frontend in Angular and the backend in Java Spring Boot. At the backend we are using microservices architectures and there are 3 core services namely Product, Order and Payment along with 2 backing services, like a API Gateway and Eureka discovery client.

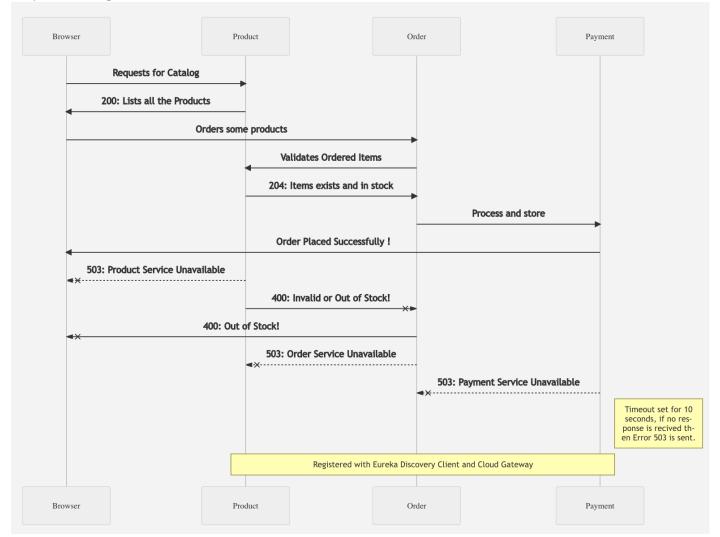

## Project Type:

Microservice Webapp

#### Architecture:

#### Sequence Diagram:

## Share Learnings:

# Nitin Kumar:

- 1. Implementing a Microservices Application using Java Spring Boot
- 2. Making UI with Angular and connecting with a Backend Service.
- 3. Resolving CORS issue in a standard way.
- 4. Working with various tools and technologies such as:
  - 1. GitHub Organisation feature
  - 2. GitHub Actions
  - 3. SonarQube configuration and integration
  - 4. Writing Unit Test using JUnits
  - 5. Selenium: Writing test cases, POM design pattern, execution using TestNG
  - 6. Jenkins: Use and Purpose, Pipelines, Declarative Pipelines
  - 7. Amazon EC2: Setup and Configuration
  - 8. Docker, Docker-Compose
  - 9. Deploying image using Jenkins and integration.

#### Challenges:

- 1. Working with microservices architecture.
- 2. Deployment of the microservices.
- 3. Learning various tools such as Sonar, Jenkins, Docker, and IAAS Amazon

#### Problem faced and resolved:

- 1. CORS: When we make request using a frontend client like in our case: an Angular App. We get this error, as the backend and server are running on different ports (in local context). In order to solve it we read about it online and implemented a configuration file which allows the request from a whitelisted client.
- 2. Communication between various services: In order resolve this we are using Eureka Discovery Client, using which we call the services and in a service in unavailable the request gets timed out and the flow continues. Here we used circuit breaker pattern provided by Eureka.3
- 3. Dockerization: Dockerization was a little tricky, when working with various docker images. Upon reading we got to know about Docker-Compose and it is built for this purpose only.

# DevOps:

## How frequently you deploy:

With every single stable build we deploy the images of our services to docker hub.

# Cycle time to build / Test / Deploy:

## **Stage View**
